Intelligence for the physical world

AR without glasses.

Intelligent projected light that guides people step by step through real tasks.

Jonathan Solomon / Founder & CEO
hi@lightcompany.ai / lightcompany.ai

The world becomes the interface

A screen can describe an action.
Projected light shows exactly where it belongs.

Our vision is AR that understands the task, places guidance on real surfaces, checks progress, and shows the next step.

Robotics evaluation is our first commercial wedge.

Broader task understanding and end-to-end guidance are the product vision.

The test changes before the robot moves

Every robot trial begins with a physical reset.

A person puts objects back. A small change in position or orientation changes the next input.

When the result changes, the team must separate a policy change from a setup change.

Initial conditions are the physical starting state of a test.

Physical AI needs reliable comparisons

Uncontrolled setup variation can distort which model a team keeps and which failure it investigates.

More trials can mean more work without resolving what caused the difference.

Prism makes the starting state repeatable and verifiable.

Prism guides and verifies the reset

01

Define and project

Choose a target state. Project placement guidance into the workspace.

02

Reset and verify

The operator places the objects. Cameras check the setup against the target.

03

Run and record

The guidance turns off. The robot runs against a known starting state.

Repeat the same conditions to compare policies, or vary conditions deliberately to investigate failures.

10 units sold and deployed

3 customers

5

Enact

Purchased after one demo

4

New Theory

Units in the field

1

Trossen Robotics

Pilot underway

$15,000 hardware sales value at $1,500 per unit

Founder-reported sales and deployment. Sales value does not establish cash collected.

Five units after one demo

10x

evaluation efficiency by run count

300–400 runs before. About 30 with Prism.

Enact needed consistent initial conditions. After seeing projected setup guidance, it bought five units.

Founder-reported. 10x uses 300 ÷ 30. Equal statistical confidence and total time savings are not independently established.

Lower variation between evaluations

92.5%

reduction in reported variability

40% before. 3% with Prism.

A clearer comparison begins with a more consistent physical input.

Company-reported field result. (40 – 3) ÷ 40 = 92.5%. Metric definitions and trial logs remain outstanding.
This is separate from Enact’s run-count result.

More data can still leave gaps

A robot can fail in a position or orientation that the training data barely covers.

Planned capability maps would show failures and undersampled states: conditions with too few useful examples.

Teams could target those gaps, collect relevant data, retrain, and test the same conditions again.

Roadmap. Failure maps alone do not establish that missing training data caused a failure.

Revenue grows with the work

$1,500

Current hardware price per unit

Software pricing under consideration

A subscription, potentially around $100 per month, or usage-based pricing for completed workflows.

Pricing is not final. With usage-based billing, more training, testing, and data collection through Prism can generate more paid use.

A station can support recurring software use

Illustrative annual usage revenue

10 stations	$250,000
100 stations	$2.5 million
1,000 stations	$25 million

Scenario: $1 per verified reset × 100 resets per day
× 250 operating days per year.

Illustration, not a forecast or current pricing. Assumes every station pays at that use level. Excludes hardware revenue.

Robotics first. Guided physical work next.

Today	Repeatable robot evaluation through projected guidance and camera verification.
Next	Failure maps and targeted data collection, with software customers use and pay for repeatedly.
Vision	Step-by-step AR for assembly, repair, training, and other work on real surfaces.

Expansion requires task-specific knowledge and verification. These broader applications are planned.

$1.5 million

Build dependable stations and recurring software revenue.

Standardize installation and improve reliability.

Build usage-based software and expand paid workflows.

Measure repeatability and document customer outcomes.
